

# **Equity and equality: How data visualizations mediate teacher sensemaking about racial and gender inequity**

**Daniel Reinholz and Niral Shah**

*This manuscript focuses on the role of data analytics in mediating how teachers make sense of racial and gender inequity in patterns of student participation in their classrooms. Five middle school math teachers participated in a year-long professional development program, centered around data analytics generated by the EQUIP observation tool (<https://www.equip.ninja>). Through our analyses we documented a total of six distinct teacher logics used to make sense of the data. We discuss how these logics were mediated by particular features of the given data visualizations. We close with recommendations for the future study of the design of data visualizations and a discussion of implication for mathematics teacher education.*

## **Introduction**

Data are central to educational improvement in the US. At a classroom level, data support professional development. Teachers need meaningful data about their teaching to support ongoing learning and improvement to practice. In particular, given the ongoing and urgent calls to improve racial and gender equity in mathematics education (e.g., Martin, 2019), teachers need actionable data identifying and describing racial and gender inequities in their classrooms. This manuscript focuses on data generated by the EQUIP observation tool (Reinholz & Shah, 2018), which was designed for precisely this purpose.

This manuscript draws upon data from a yearlong professional development effort with five middle school mathematics teachers (Herbel-Eisenmann & Shah, 2019). The professional development was organized around iterative cycles of instructional improvement, with EQUIP analytics being used to structure each cycle of reflection and revision of teaching practices. Here we focus on instructors' sensemaking as they processed the analytics. This work is driven by the research question: *What logics did teachers draw upon to make sense of racial and gender inequities in student participation, as presented by EQUIP analytics?*

This work makes multiple contributions. First, although data are routinely used in professional development (e.g., Horn et al., 2015), little research explicates associated teacher logics, which we define as the explanations that teachers use to rationalize the data. Thus, the present work pushes the field forward by focusing deeply on sensemaking around particular analytics, a level of granularity required for educational designers to create more effective visualizations. Second, most observation tools only provide data at the level of a classroom. That is, such tools cannot speak to the experiences of a particular group of students, such as Black girls. In this way, the EQUIP analytics—which are focused on social marker groups—provide a window into understanding how teachers reason about equity.

## **Theoretical Background**

### **Participatory inequities in mathematics classrooms**

This manuscript focuses on *participatory equity*, which concerns the fair distribution of participation and opportunities to participate in the classroom (Shah & Lewis, 2019). Student participation is consequential to equity for multiple reasons. First, research shows that

participation is an important mechanism for learning content (Banes et al., 2018), for instance, because learners consolidate their learning when they explain their thinking (Chi et al., 1994). Second, when students make their ideas public, it allows them to receive feedback from peers and the instructor, which is also important for learning (Reinholz, 2016). Third, identity development is closely linked to participation (Nasir, 2002), and when students identify with a discipline, it creates a sense of belonging that is essential for persistence (Lewis et al., 2016).

Simultaneously, research shows that women and racially minoritized students tend to receive disproportionately fewer and lower-quality participation opportunities in math classrooms (e.g., J. B. Ernest et al., 2019; McAfee, 2014). These inequities arise because classrooms are not immune to oppressive structures such as patriarchy and white supremacy. For instance, young girls face stereotype threat, teachers' biased impressions of their competence, and the transference of gendered math anxiety from their teachers (Lubienski & Ganley, 2017). Similarly, racially minoritized students face hostile racial discourses, microaggressions, and low teacher expectations (e.g., Larnell, Boston, & Bragelman, 2014). These systems of oppression also work together, when students are marginalized along multiple strands of their identities (Crenshaw, 1990). All of these phenomena play out in ways that inhibit women and racially minoritized students from participating in mathematics classroom discourse.

Given that these oppressive structures are systemic in society, clearly there is a limit to the work any individual teacher can do to dismantle them in their classroom. Nonetheless, one plausible entry point into grappling with these larger systems is through addressing implicit biases. Implicit biases impact one's thoughts, beliefs, and actions in subtle, unconscious ways that are not visible to an individual (Greenwald & Banaji, 1995). Implicit biases in mathematics are driven by problematic stereotypes such as "Asians are good at math" (Shah, 2017) or the

“white male math myth” (Stinson, 2008), which create a “popular image of mathematics” as “difficult, cold, abstract, ultra-rational, important and largely masculine” (Ernest, 1992, p. 53). Even teachers who do not endorse such stereotypes are impacted by them subconsciously, for instance, in the expectations they have towards girls (Robinson-Cimpian et al., 2014), or whether they invisibilize students of color in their classrooms (Shah, Herbel-Eisenmann, et al., 2020). These biases also play out between students, for example, when they engage in sexist microaggressions during small group work time (J. B. Ernest et al., 2019). Addressing implicit biases first requires that teachers to be aware of the impacts of implicit bias within their classrooms. In this way, data can play an important role in illuminating what are otherwise invisible phenomena, as we now elaborate.

### **Data for instructional improvement**

The use of data to improve instruction is ubiquitous (Datnow & Hubbard, 2016). However, the majority of these data come from standardized tests (Farrell & Marsh, 2016; Van Gasse et al., 2016). Unfortunately, research suggests that test-based, data-driven accountability initiatives – even those that are ostensibly framed about improving equity – can actually result in the exacerbation of *inequity* at a classroom level, as they frame students from a deficit perspective and constrain teacher agency (M. Braaten et al., 2017). The underlying logic of test-based accountability focuses on current inequities in performance, rather than the historical, structural antecedents that actually led to such inequities (Garner et al., 2017).

Given the limitations of focusing on student test scores, researchers argue instead for the need for data attending to the quality students’ classroom experiences (M. Braaten et al., 2017). This has spurred the development of the equity analytics paradigm, which focuses on how data

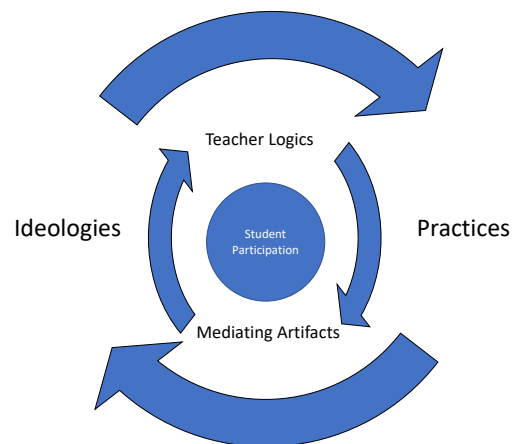

describing patterns of student participation can be used to promote instructional improvement and lead to deeper conversations about dismantling systems of injustice (Reinholz & Shah, 2018). Still, a key consideration is the type of teacher sensemaking that takes place around data (Schildkamp, 2019). That is, how do teachers analyze and interpret data, and how does this process relate to their instructional improvement goals and practices? Research shows that the particular teacher logics utilized are central to the efficacy of the sensemaking process (Horn et al., 2015). Moreover, sensemaking is dependent on the particular context and approach. Thus, we introduce a conceptual model for understanding teacher sensemaking around racial and gender inequity in student participation.

### **Conceptual Frame**

Figure 1 introduces a conceptual model for how teachers make sense of student participation data. Our model breaks the larger sensemaking process into four components. The inner circle focuses on teachers' moment-to-moment sensemaking through *teacher logics*, which are the explanations teachers use to rationalize the data, and *mediating artifacts*, which are the particular features of the data visualizations that influence sensemaking. The outer circle focuses on comparatively more stable constructs, which teachers may draw upon as they generate explanations in the moment. These constructs are *ideologies*, which are broader ways of thinking (e.g., about race, gender, teaching) and *practices*, a teacher's concrete teaching techniques.

## Figure 1

*Conceptual model for teacher sensemaking of student participation data.*

### **Inner circle: Teacher logics and mediating artifacts**

The inner circle focuses on the moment-to-moment sensemaking that occurs when teachers engage with data representing student participation patterns. This sensemaking involves an interplay between *teacher logics* and *mediating artifacts*. Given the complex, multidimensional nature of student participation patterns, there are typically multiple plausible explanations (i.e. *logics*) for any given pattern. For instance, a teacher might attribute a student's lack of participation to: characteristics of the student (e.g., they are shy), the student's circumstances (e.g., they don't have homework support at home), their race (e.g., my Latino students are struggling), or other situational factors (e.g., the student just broke up with their

partner). When teachers fixate on immutable characteristics of students, rather than situational factors, they may miss their own role in empowering or marginalizing their students.

While teachers often have a set of preferred explanations for why students do or do not participate, the particular explanations that teachers draw on are influenced by *mediating artifacts*, or the particular data representations of student participation. For instance, if participation is not disaggregated by student social markers, it will necessarily obscure racialized and gendered phenomena. Types of representations also matter. For example, a pie chart could cue the zero-sum thinking (who gets the biggest piece of the pie), while bar charts of individual students would draw attention to particular individuals who are left out. Although it is known that the nature of data representations matters (e.g., Saket et al., 2019; Szafir, 2018), little is known about the role of particular representations in teacher education.

### **Outer circles: Ideologies and practices**

Ideologies are interpretative frameworks—consisting of various cultural representations—which are used to make sense of the social world (Hall, 1985). For example, in education, a student’s difficulties in learning mathematics content may be explained by describing the student as a “slow learner” (Horn, 2007) or “learning disabled” (McDermott, 1993). They might also be described by false racial narratives (e.g., “Latinx students don’t care about school”; Gonzalez & Ayala-Alcantar, 2008). Often, these ideologies represent negative generalizations about particular groups, but they need not be negative.

Ideologies influence how a teacher interprets classroom situations. For instance, if a teacher believes a group of students is lazy, they might initiate punitive measures. In contrast, a teacher who recognizes the systemic barriers would instead work to remove those barriers and

provide appropriate support. Ideologies also indirectly impact teaching through implicit biases, for instance, impacting who a teacher calls on and how (Shah, Herbel-Eisenmann, et al., 2020).

Teaching practices can also impact ideologies. For example, if a math teacher only asks low-level questions to Black students, thereby denying them meaningful participation opportunities, the teacher will be unlikely to see the underlying brilliance of Black students (cf. Bullock et al., 2012). Thus, oppressive ideologies become a self-fulfilling prophecy. Teachers may also actively disrupt racism, for instance, through *assigning competence* (Cohen & Lotan, 1997), which can shift classroom hierarchies. Shifting these hierarchies results in new patterns of participation. In witnessing the abilities of students as they participate, it provides a counternarrative to negative ideologies about mathematical ability.

## **Method**

### **Context**

Research took place at Northstar Middle School (a pseudonym), a suburban Midwest school. Teachers at Northstar had a longstanding (5-year) collaboration that involved action research with researchers at a local university. The present work was motivated in part by a growing Latinx student population in the district, which had shifted classroom demographics. While prior work focused on classroom discourse, this study was the first time that teachers had access to data that described gendered and racialized patterns in their classes, which were provided by the EQUIP classroom observation tool (described below). All names below are pseudonyms.

### **Participants and Design**

Five mathematics teachers participated in the study (all white; four women, and one man). These teachers were chosen because they had multiple years of experience engaging in action research, and also considerable teaching experience across the board; all had been teaching for 10 to 30 years. Given these characteristics, the teachers were experienced reflecting on their teaching practice, but they had never done so with EQUIP data. This made them ideal participants in a study focused specifically on EQUIP data. For this study, each teacher selected one “focal class” for action research with EQUIP.

The study took place over a single academic year. Initially, the research team met with participants and shared a presentation on implicit bias, the EQUIP tool, and the differences between equity and equality. The work over the year to come was then organized by iterative research cycles of video observation, coding, reflection, and changing practices. Each research cycle lasted roughly six weeks, with each teacher videotaped ~3-4 each per cycle (with a total of four cycles). These videos were coded with EQUIP, so that data analytics could be provided to the teachers. To end each cycle, there was a half-day reflection meeting where teachers watched videos of their teaching, discussed their data with colleagues in larger groups, and debriefed (~30 minutes) with a member of the research team. The debriefs focused on EQUIP analytics from that cycle of observations. Debriefs aimed to help teachers process the data and to develop concrete action plans to improve equity in their classes.

### **Data Sources**

The present analysis focused on the 30-minute teacher debriefs from the four cycles of reflection with EQUIP data, which followed a semi-structured protocol (guiding teachers to look at their data). Our analysis also drew upon pre- and post- interviews that were conducted with

each teacher to provide context for understanding the debriefs. All of these data were audio recorded and transcribed. The pre-interview focused on background information, such as childhood experiences around race and gender, professional trajectory, and pedagogical approach. The post-interviews allowed for reflection on lessons learned throughout the year. Finally, we used actual EQUIP analytics as a secondary data source, when necessary, to understand what the teachers and researchers were discussing in the debriefs.

## **EQUIP**

The EQUIP classroom observation tool was used to provide teachers with data describing disaggregated patterns of student participation (Reinholz & Shah, 2018). In prior work, EQUIP has been used both as a research tool for documenting inequities in classroom participation (e.g., J. B. Ernest et al., 2019), and also as a professional development tool to provide real data to instructors that they can use to improve their teaching (e.g., Reinholz, Bradfield, et al., 2019; Reinholz et al., 2020; Reinholz, Stone-Johnstone, et al., 2019; Shah, Christensen, et al., 2020). Building on this body of work, the focus in this paper is different, and turns to the data analytics in the tool itself and how they support teacher sensemaking.

Conceptually, EQUIP describes how classroom participation *is* distributed; it cannot describe how participation *should* be distributed. Rather, the purpose of EQUIP is to provide analytics—without judgment—that teachers and coaches can use together to support instructional improvement. In general, the EQUIP developers view equality as a baseline *towards* equity (Secada, 1989), recognizing that minoritized students typically get *less than* an equal share of opportunities to participate. Thus, if EQUIP analytics indicated that a minoritized

population was getting less than equal share of participation opportunities, it would be viewed as a potential area for teacher intervention.

In EQUIP, the unit of analysis is a *sequence* of talk; a sequence starts when a new student speaks and ends when another student speaks. With this definition, any length of interaction between the instructor and a single student is considered one sequence. On the other hand, if two students are having a conversation, then a new sequence begins each time a student speaks. The particular design decision within EQUIP to start a new contribution each time a new student speaks was two-fold: 1) because each coded contribution corresponds to a single student, demographic information can be attached to individual students, which can then be aggregated in the analysis process, and 2) this decision leaves little doubt where to start a new sequence, which supports a high level of interrater reliability, even with coders who are relatively new to the process. As a result of this decision, in a classroom where there is more student-to-student talk, there will be a relatively higher number of sequences coded.

To code with EQUIP, an observer 1) chooses discourse dimensions (what will be coded), 2) chooses demographic categories (race and gender in this study), and 3) creates a student roster that includes demographic information. The EQUIP observer is typically a coach or researcher, but in some prior studies, teachers have actually coded videos of their own teaching (Shah, Christensen, et al., 2020). In this study, all teachers used the dimensions of *solicitation type*, *student talk type*, and *student talk length* (see Table 1), as well as individualized custom dimensions. These dimensions allowed the teachers to go beyond quantity of participation to also understand the quality of opportunities afforded to different students (cf. M. Braaten & Windschitl, 2011).

We used the EQUIP app (<https://www.equip.ninja>) to streamline coding. EQUIP is a free, open-source tool that supports researchers using the EQUIP protocol. The app can be used either real-time or as a platform for analyzing previously recorded classroom videos (which was the case in this study). EQUIP does not record a teacher’s classroom and efficiently allows for coding without transcripts of classroom video. The EQUIP app guides a user to set up a classroom seating chart, which is also used as the interface for coding (see Figure 2). When a user clicks on a student’s desk, they are given the option to code that student’s participation, and EQUIP keeps a running log of coded participation, which provides the raw data for analytics that can be generated (as shown below).

**Table 1**

*Codes used to capture the quality of student discourse.*

Code	Subcode	Definition
Solicitation Type	Why	Instructor asks student to explain/justify their reasoning
	How	Instructor asks for a student’s solution method
	What	Instructor asks a student to read part of a problem, recall a fact, or give a numerical/verbal answer
	Other	Instructor asks a general question (e.g., “What did you think?”)
	N/A	Instructor does not ask the student a question
Student Talk Type	Why	Student explains/justifies their reasoning
	How	Student describes solution method
	What	Student reads part of the problem, recalls a fact, or gives a numerical/verbal answer to a problem
	Other	Student asks a question or says something nonmathematical
Student Talk Length	21+ words	21+ words typically corresponds to multiple sentences
	5-20 words	5-20 words typically corresponds to one sentence
	1-4 words	1-4 words corresponds to a short statement (often a single-word answer)

To generate analytics, EQUIP combines the coded sequences corresponding to individual students with demographic information, so that analytics can be generated about specific groups of students (e.g., Black boys). One such analytic is an equity ratio, which compares the *actual*

distribution of talk-based participation to the *expected* distribution, using classroom demographics as a baseline. For instance, if a class is 60% women, but they only receive 30% of the questions, the ratio would be  $\frac{1}{2}$ , indicating a *disproportionately low* level of participation. A ratio of 1 indicates that a group is participating *proportionally* to its demographic representation in the class, and a ratio  $> 1$  indicates *disproportionately high* participation.

## Figure 2

Screenshots from the coding interface in the EQUIP web app.

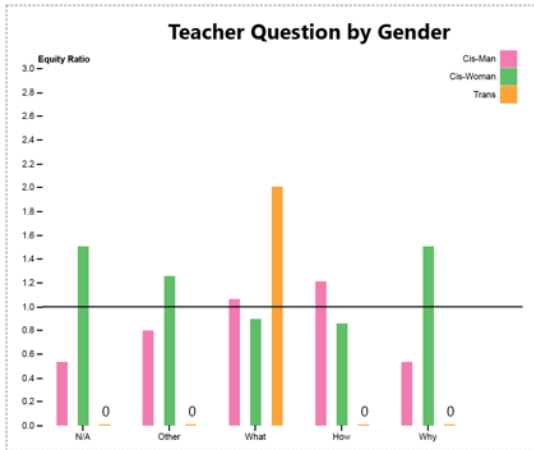

The figure consists of two screenshots from the EQUIP web app. The top screenshot shows a classroom grid and a table of observations. The classroom grid is titled "FRONT OF CLASSROOM" and lists 16 students in a 4x4 grid: Brenda, Elan, Carlos, Debra; Candace, Jalen, Janelle, Halona; Faye, Garrett, Jennifer, Joe; Joey, Julisa, Kristy, Lark; Lawrence, Lequoia, Marcus, Monet; Nia, Niral, Parker, Phoung; Rick, Russell, Sam, Silvia; Tama, Thomas, Wendy, Zahra. The table below the grid shows observations for five students: Marcus, Jun Yi, Maggie, Geneva, and Tariq. Each row includes columns for Time, Teacher Question (Type), Teacher Wait Time, Student Talk (Length), Student Talk (Type), and Microaggressions (Type). The bottom screenshot shows a form titled "Enter a contribution for Ta'veon" with four dropdown menus: Teacher Question (Type) with options Why, How, What, Other, N/A; Teacher Wait Time with options < 3 seconds, > 3 seconds, N/A; Student Talk (Length) with options 1-4 words, 5-20 words, 21+ words; and Student Talk (Type) with options Why, How, What, Other.

The EQUIP web app can also automatically generate data visualizations corresponding to the EQUIP observation protocol. Here, in this manuscript, we focus on two types of data visualizations that can be generated within EQUIP. Figure 3 is the equity ratio graph describes the breakdown of a particular discourse dimension (in this case, teacher question) according to a

demographic category (in this case, gender). Figure 4 shows the individual student graph, which shows how much each individual spoke in class. These visualizations provided the basis for professional development with teachers in the study.

**Figure 3**

*Equity ratio graph for gender. The line at “equity ratio = 1” represents equality, or participation proportional to demographic representation.*

**Figure 4**

*Individual student graphs. Each bar shows the participation of one student. In this figure, student names are redacted for anonymity.*

Lastly, we recognize that students may be engaged in a variety of meaningful, but nonverbal, forms of participation (e.g., O’Connor et al., 2017; Radford, 2003), which are not captured. Because no tool can capture all meaningful aspects of classroom activity, EQUIP focuses on verbal participation, given its important role in the learning process (Banes et al., 2018). A tool designed to shed light on these forms of participation would provide different insights for teachers to improve equity in their classrooms.

## **Analytic Methods**

The goal of our analysis was to understand the logics that teachers drew upon when interpreting racial and gender inequities in student participation. Thus, we aimed to develop grounded theories about one of the four components of our conceptual model of teacher sensemaking. Within each *teacher logic*, we make connections to *mediating artifacts*, *ideologies*, and teaching *practices* (shown in *italics* in the results below). The purpose of connecting to these other constructs is to illustrate how *logics* are connected to other aspects of sensemaking but developing deeper theories of the other constructs is beyond the present analysis.

Data analysis followed a process of qualitative thematic analysis (Boyatzis, 1998) and constant comparison (Krahtwohl, 1998). Such an analytic approach was appropriate because there were no a priori coding schemes that characterized the different logics teachers draw upon. By applying grounded theory to the transcripts of teacher sensemaking, we created an emergent thematic framework of how teachers made sense of patterns of racial and gender equity data.

The first step of analysis was open coding teacher debriefs. Open coding aimed to identify all instances of teachers interacting with EQUIP analytics or describing insights they gained from the analytics. At the end of this step, the first author had generated annotated transcripts of teacher debrief conversations that highlighted the segments of interest. The second step was to generate initial categories to group together the codes that were generated in the first step. During this step, the first author generated seven initial categories.

The third step involved a thematic analysis to determine and summarize the predominant categories. At this point in the process, both authors met to discuss the categories. After this discussion, the categories were refined to the six predominant categories described below in the results. Step four involved the first author analyzing the data corpus again to look for evidence in

favor of and against the preliminary themes. These themes were categorized by the logics that teachers used to make sense of the data, with connection to features of the data visualizations.

## Findings

We found that teachers employed a variety of *logics* to make sense of the data visualizations provided by EQUIP. Table 2 organizes six predominant logics according to reasoning about aspects of teaching related to social marker categories or describing individuals.

**Table 2.**

*Summary of teacher logics.*

Level	Teacher Logic	Example
Social Marker Groups	Equality	“I’d like to see all of the bars right at the one [the equity ratio=1 line].”
	Balance	“I need for girls and boys to be balanced in their participation.”
	Reparation	“I like to see that my Latinx students [a minoritized group] are participating above 1.”
Individuals	Coverage	“I want to make sure that all of my students are participating.”
	Focus	“I notice that Dante had a low level of participation.”
	Redistribution	“Andy is dominating the class discussions, and I need him to talk less so other students can participate.”

### Social Marker Groups

The primary goal of the EQUIP analytics was to draw attention to different social marker groups, which was achieved through equity ratio bar graphs. The “equity ratio = 1” line was a salient feature for teachers. Even though the research team clearly stated, “equity is not equality,” teachers often talked about this line as though it was the “correct” or “target” value for equity. This mediated reasoning about equity in a variety of different ways, as we now elaborate.

### *Equity as Equality*

A common *logic* expressed by teachers was equity required that their students have equal participation during class sessions. This *logic* was *mediated* by the salience of the “equity ratio = 1” line. We found evidence that 3 of 5 teachers used the line as a target value. For instance, Ms. Davis (Round 1) stated, “if [participation] were perfectly equitable, the idea is that these bars would both be at the one. What is expected is what happens. Right?” Here Ms. Davis referred to all of the bars falling exactly on the equity ratio line, or equal for all students. Ms. Davis made this statement even though the interviewer clearly stated “equal isn’t necessarily equitable” just a few moments earlier. Here, we infer that the salience of the equity ratio line cued Ms. Davis to draw upon an equity as equality *logic*.

Under some circumstances, the equity as equality *logic* can result in productive changes to *practice*. For instance, during Round 3, Ms. Davis noticed that she was “not posing as many questions” to girls in the class. She noted her strategy of using “popsicle sticks” to randomize participation did not allow her to be “intentional” about increasing participation for girls. She discussed an alternative strategy of “let[ting] the kids think I’m drawing sticks” but then intentionally selecting a girl. In this way, the presence of a minoritized group (in this case, girls) receiving less than a fair share of participation opportunities meant that an equity as equality *logic* could result in changes in *practice* that would support greater equity.

However, we also found evidence that the equity as equality *logic* can work against equity. Like Ms. Davis, Ms. Stone described that “in theory, [the bars] should all be right at the line” (Round 3). Accordingly, in Round 2, Ms. Stone stated that “I need the African American bar to come down,” because it was above the equity ratio line. Thus, the teacher concluded she needed to provide fewer participation opportunities to Black students. In this case, the analytics actually worked against the goal of providing more opportunities for minoritized students.

The pitfalls of an equity as equality ideology were demonstrated by Ms. Smith (Round 2), when she noticed that girls in her class were participating much more than boys, and said, [I]s that necessarily a bad thing that my female students are speaking so much, and do I want to shut them down? No, I don't want to shut them down. At the same time, I wanna encourage the boys to talk, and I wanna give them opportunities. The problem was, I'm not giving them opportunities. I was letting the girls run the show because they just were. What Ms. Smith notices here is that the participation for girls in her class is well above the "equity ratio = 1" line, and she sees this as a deviation from the ideal. While Ms. Smith verbalizes that she does not want to "shut down" the girls, there is an unarticulated tension. If Ms. Smith does increase the participation level of boys in her class, it will necessarily come at the expense of girls participating, given the zero-sum nature of participation.

### ***Equity as Balance***

Related to the idea of equity as equality was the *logic* of equity as balance. We found evidence that all five instructors invoked this *logic*. Sometimes these invocations were *mediated* by the visual representations, and other times it came up more generally in the absence of a particular representation. For example, Ms. Stone (Final Debrief) expressed that she was "concerned that I do see some things [the types of questions] that are not balanced [between boys and girls]." Here Ms. Stone expressed a desire for participation to not too be far away from a balanced equilibrium but did not articulate that the participation levels should be exactly equal.

In contrast to equity as equality, the *logic* of balance was more flexible. For example, Mr. Walsh (Final Interview) discussed having roughly the same amount of participation between boys and girls, such as a talk pattern of "girl, girl, girl, boy, boy, boy, girl, boy, boy, girl." Mr.

Walsh (Final Debrief) further elaborated, “I try and balance boys and girls as much as I can, but if I’m going to err on one side, I try to err on the side of girls.” As Mr. Walsh’s statements make clear, it was possible to maintain the relative equilibrium of balanced participation in a class, yet still aim to promote greater participation in favor of a minoritized group.

We suspect invocations of balance may be related to teacher’s *ideologies* about race and gender. There were 12 instances of teachers invoking balance with regard to student participation, and 11 of 12 of them focused on gender (as above), with only one instance focusing on race. In this single instance, Ms. Stone (Final Debrief) articulated a desire to balance two racial groups (Latinx and White), stating she wished they were “closer to being balanced.”

One possible explanation is the nature of the social marker categories themselves. On one hand, gender is typically, albeit problematically, construed as a binary variable. Indeed, in this study, teachers contrasted boys and girls and did not identify any nonbinary students. Given that there were only two possible categories, it is easy to invoke a sense of balance, almost like putting the two groups on the opposite sides of a scale. When teachers were given data about participation by race, multiple racial groups were always displayed. It is possible that an alternative representation, comparing only two racial groups at a time, would have more directly *mediated* cross-racial comparisons and the use of a balance *logic*.

Another possible explanation connects to *ideologies* about race and gender in the US. Mr. Walsh (Final Interview) described how broader discourses constrain what is socially acceptable, “With race it's a little tougher [than gender], because I don't generally look and say, I haven't talked to a black kid today, or had them answer a certain type of question. Boys and girls, it's pretty cut and dried, right? It's, like, man, four boys in a row have been up at the board. Can't have that...Doing this [action research project] this year has brought this

more to the forefront. Trying to do some of those same things with racial minorities that I've done with girls over the years has, I think, changed some of those patterns of participation. It's just something that I've always just been aware of with gender, and hence, implicit...I'll start, and I notice that I gave the pens to go up and do stuff to boys. I'll say, hey, pick a girl. Would I ever say, pick a black kid? Oh my God. What would happen in the room at that point?

Here Mr. Walsh contrasted the differences between talking about gender and race. It is socially acceptable to call out gender imbalance, but less so for race. As he stated, it would not be socially acceptable for him to say he was going to “pick a Black kid” as an instructional *practice*.

### ***Equity as Reparation***

The final social marker *logic* was equity as reparation. From a perspective of reparations, the “equity ratio line = 1” *mediated* thinking about a minimum benchmark for minoritized students. For instance, when talking about Latinx students, Ms. Baker (Round 5) described the equity ratio line as the “baseline that needed to be there,” and she expressed satisfaction when Latinx students, as a minoritized group in mathematics, were above that line. This particular *logic* connects to a broader *ideology* about reparations, and the notion that present imbalances (e.g., in participation) are needed to counteract historical inequities. Mr. Walsh (Round 2) used similar logic to interpret the equity ratio line,

[I]deally, I think every bar, right at the equity line, would be nice. That would look pretty, right? With what we know about girls' engagement in STEM courses later on, I would really like to see them doing more why and how than the boys. I'm good with that green bar [for girls]...[b]ecause I think we need to overcompensate a little bit. I'm good with

that. I'd like to see the green above the equity bar a little bit for those. This is a zero sum.

If one's above, the other's gonna be below. Okay, I'm good with that.

Mr. Walsh's reference to a "pretty" visual distribution points to the salience of the "equity ratio = 1" line as a perceptual anchor. From this baseline, he then provided a correction to overcompensate for historically marginalized students. Mr. Walsh also articulated the reparation view other times, for instance, when he said (in Round 4), "The fact that the Latino one is above the equity ratio on both of those I'm happy that I was able to be pretty intentional about that."

## **Individual**

In addition to reasoning about social marker groups, teachers also attended to participation levels for their students as individuals. At times individual logics were used to think of all students as equal (ignoring their backgrounds and social marker identities), while at other times social marker information was used to interpret the participation of individual students.

## ***Equity through Coverage***

Teachers used the individual analytics to ensure that all students had at least some participation. Thus, the goal was to achieve coverage of the whole class, and if some students never participated, it signified inequity. All five teachers used equity through coverage *logic*. This logic was *mediated* by looking at bars where students had zero participation. Teachers, like Ms. Smith (Round 3), stated "20 out of 30" students participating as "disappointing," and Ms. Stone (Round 3), exclaimed "wow 17 out of 29. That's terrible." Similarly, Ms. Davis (Final Debrief) described, "I was just viewing it as, are all students participating?" In all of these cases,

the teachers wanted to make sure that all students had a chance to participate, regardless of their backgrounds.

The coverage *logic* drew attention to students who had zero participation. In her Final Interview, Ms. Baker discussed the “kids at zero,” through a metaphor of kids swimming, “Some kids just love to swim. They're splashing around. They're swimming out to the raft, jumping off the raft, swimming back, right? They're not even thinking about it. They're just swimming, right? There's some kids that are wearing floaties, got them on their arms, whatever, the kid things, whatever. They're pretty comfortable with that. With some support, they're fine. We've got some kids, the kids at this other end, who are tied to cement blocks. They're not thinking about swimming. They're thinking about, how the hell do I keep my head above water?”

Ms. Baker described how she has always “struggled” to support those students, but that she “just focused on them more this year.” Here, what Ms. Baker describes is a general recognition of the students who were not participating, but with the visual salience of “zeros” rather than a participation bar, it made her focus more attention on those particular students.

### ***Equity through Focus***

The individual student graph also provided a means for teachers to focus on individual students. For instance, Ms. Baker (Round 1) said “I’m really surprised at how infrequently...Brian, Mark, and Kevin [were called on]. I would have expected them to be called on more.” Here, the visual representation of students who were not called on often either having a “zero” above their name, or a bar with a short height, made it easy for teachers to focus on them. This awareness could then be used to implement *practices* to increase their participation.

Notably, teachers also used the social marker graphs to identify individual students to support. Teachers often coordinated between the individual and social marker levels, using what they knew about their students both as individuals as members of particular groups. To illustrate, consider Mr. Walsh in Round 3 and Round 4 debriefs. In Round 3, the interviewer drew Mr. Walsh's attention to Latinx and Black students in the class. Recognizing that there were two Latinx students, Mr. Walsh used what he knew about them as individuals to interpret the "green bars for Latinx students." He said "Marina's...really taking the bull by the horns, and she's got a ton of confidence." In contrast, he mentioned "Jasmin, still, I worry about. If we looked at these contributions and which was which, I think Marina is dominating that." As these statements make clear, Mr. Walsh first noticed the aggregate description of Latinx student performance, and then disaggregated it into individual students within that category. Mr. Walsh further elaborated how he was able to build "a relationship with" Marina, which made a huge difference. He contrasted this to Jasmin, who he didn't think "trusts" him.

Similarly, Mr. Walsh used what he knew about his three Black students as individuals, to understand the aggregate participation of Black students. Mr. Walsh described Luke as "smarter than heck," while he said the other two students were "giving up" on him. Mr. Walsh described in depth how he was reaching out to Mo and trying to provide additional support. In the end, he concluded that he "was not happy with where we are with those three right now. That's a major issue for me." At the end of the debrief, Mr. Walsh changed his *practice* to include specific student names in his lesson plan to think strategically on how to incorporate these students into his lesson plan. During Debrief 4, Mr. Walsh reflected on this process. He stated that,

I think it's a mixed bag. I think for a couple of kids it worked really well. Jasmin and Mo particularly...Part of the mixed bag is that I think assigning competence, that maybe I

was looking for too quick of a turnaround for their attitudes, for their confidence to grow, and it hasn't. That might have been looking for a magic bullet.

What Mr. Walsh's reflection shows is how he was able to use the quantitative data, which described disproportionately impacted groups in his classroom, in order to attend to specific students and incorporate them into his lesson planning to elevate their participation. Later in the same debrief, Mr. Walsh had a slightly more positive outlook of the focus on individual students,

That's one of the other things I noticed and was going to bring up just in terms of voluntary participation that if you want to draw a broad, general connective conclusion the kids that we focused individual attention on, it's like the great Eye of Sauron, when we focus this laser light on certain kids it clearly changes their participation.

Here, Mr. Walsh describes how the individual analytics supported him to focus on particular students, and that having the explicit focus was important to improving their participation.

### ***Equity through Redistribution***

Teachers were reluctant to use the final *logic*, of redistribution. The *logic* of redistribution is that dominant students can take up a disproportionate amount of space, preventing other students from participating. In this particular study, we found that teachers did not utilize this way of thinking, even when explicitly prompted.

For example, in Round 3, the interviewer noted that one of Ms. Davis's students, Bruce, had 60 out of the 300 participation sequences, or 20% of them, in a classroom with 30 students. Ms. Davis exclaimed "that is crazy." Despite the interview's suggestions to reduce the amount of participation from this student, she justified his participation, saying "I know he doesn't feel that in all of his classes." She continued that in other classes he gets "shutdown, or he tries to share

and nobody calls on him.” In her final debrief interview, Ms. Davis returned to Bruce, saying that she did not “ask him to temper his response in the class,” because she was aware of his frustration of how he was treated as a Latino boy in the school.

Why did teachers refrain from using this logic? On one hand, there was nothing perceptually in the data visualizations that would make teachers think about reducing participation from a single student. Although a tall bar on the individual graph would stand out, what clearly stood out more for teachers were the students who were participating little to not at all. It’s possible another visualization (like a pie chart), would have influenced teacher thinking differently. At the same time, increasing student participation is more socially acceptable than thinking about reducing a students’ participation, even if such a move might actually support equity by creating space for other students.

### **Discussion**

Our findings highlight how data visualizations supported teacher sensemaking of racial and gender inequity in classroom participation. Moreover, teachers did this without dehumanizing students: social marker patterns were constantly compared with the teacher’s professional knowledge and what was known about students as individuals. The data analytics allowed teachers to identify inequities both for groups and individual students, which they had the potential to address with intentional changes to their teaching practices.

We identified a total of six prevalent teacher *logics* for making sense of equity. For social marker groups, teachers conceptualized equity as equality, balance, or reparation. We found that a single representation could mediate a variety of ways of thinking, depending on teacher ideologies. The "equity ratio = 1" line was seen as a target value for all groups to achieve (equity

as equality), a general guideline for student participation (equity as balance), and as a minimum baseline for students from minoritized groups (equity as reparations).

Teacher logics for individuals aimed to create equity through coverage, focus, and redistribution. In this study, we only found evidence of the coverage and focus logics. All teachers utilized the coverage logic. It was intuitively appealing that all students should participate at least sometimes, and the large zeros above empty bars made this perceptually salient. Similar to the coverage logic, the focus logic aimed to consider the experiences of particular students and how to increase their participation. When students were viewed this way, background information about their social marker identities, experiences in other classes, or home life were drawn upon by teachers as relevant. The final logic, redistribution, was suggested by the interviewers but never adopted by teachers.

One limitation of the study is that the sample consisted entirely of white teachers. Research shows that white people in general (Bonilla-Silva, 2003; O'Brien & Korgen, 2007), and white teachers specifically (Hinojosa & Moras, 2009), much more readily embrace a colorblind ideology and may be averse to seeing the oppressive impacts of racism in society. As such, we suspect that in a similar study with teachers of color, they may have been able to more readily connect structural racism to impacts on individual students in their classroom, which would have influenced their interpretation of the data analytics. Indeed, preliminary evidence from our professional development work does suggest that teachers of color may be better equipped to interpret and immediately act upon data showing racial inequity (Reinholz, Stone-Johnstone, et al., 2019). Nonetheless, we do find that evidence showing that the white teachers in the study were able to productively grapple with racial inequity in their classes is a promising sign.

## Implications and Future Directions

This study has a number of implications for teacher education. First, we found that providing disaggregated data analytics prompted teachers to reflect on racial and gender inequities in their classrooms. In this way, the data analytics helped move beyond thinking about the classroom as a whole, to draw attention to individual students and social marker groups. We argue that this is a necessary step to take seriously calls for equity in mathematics education.

Second, we demonstrate that simply providing data is not enough. For instance, we documented cases where teachers utilized an equity as equality logic in a way that could actually cause harm to students from minoritized groups (e.g., girls, Black students), because their participation was higher than would be expected by demographic representation alone. A single data representation can be interpreted using a variety of logics. Thus, it is important for teacher educators to consider the complex relationships between ideologies, practices, mediating artifacts, and teacher logics, to help promote productive lines of reasoning for teachers.

Third, our work suggests that particular representations have salient features that could mediate particular types of thinking. In general, we found that the “equity ratio = 1” link seemed to prompt teachers to use equity as equality, although it could also be used to promote other ways of thinking. Similarly, the presence of zeros over empty bars in the individual student bar graph drew special attention to the students who were not participating. Accordingly, we suspect that through intentional design, it may be possible to create new data visualizations that nudge teachers to use particular logics to reason about students. For example, if we wanted to invoke a sense of balance between racial groups, it might be achieved more productively by only visualizing participation from two groups at a time, rather than showing all of the racial groups in the class. We further hypothesize that by creating visuals that focus explicitly on target

groups, it could help teachers do better to support them, while avoiding zero-sum pitfalls. The ways in which analytics can be designed to explicitly cue particular forms of thinking is an important area of future research.
